44. Data Integrity and Protection

Operating System: Three Easy Pieces

D Old days: fail-stop, Now: Latent-sector Errors and block Corruption

□ LSEs

- Arise when Head crash, cosmic rays, material wear out, ... etc
- **Detectable** and correctable (sometimes) via ECC

- **Corruption**
 - Firmware bugs, faulty bus or connections, ...
 - Not detectable by the disk itselft (e.g., copy a block in the wrong loc.)
 - Silent faults

 Common and worthy of failures are frequency of latent-sector errors(LSEs) and block corruption. (3 years, 1.5 million disks, cheap disks 10x more prone to failures)

	Cheap	Costly
LSEs	9.40%	1.40%
Corruption	0.50%	0.05%

Frequency of LSEs and Block Corruption

- Frequency of latent-sector errors(LSEs)
 - Costly drives with more than one LSE are as likely to develop additional.
 - For most drives, annual error rate increases in year two
 - LSEs increase with disk size
 - Most disks with LSEs have less than 50
 - Disks with LSEs are more likely to develop additional LSEs
 - There exists a significant amount of spatial and temporal locality
 - Disk scrubbing is useful (most LSEs were found this way)

- **Block corruption**:
 - Chance of corruption varies greatly across different drive models. Within the same drive class
 - Age affects are different across models
 - Workload and disk size have little impact on corruption
 - Most disks with corruption only have a few corruptions
 - Corruption is not independent with a disk or across disks in RAID
 - There exists spatial locality, and some temporal locality
 - There is a weak correlation with LSEs
- A reliable storage system, requires machinery to detect and recover from LSE and block corruption

D Latent sector errors are easily detected and handled.

D Using **redundancy mechanisms**:

 In a mirrored RAID or RAID-4 and RAID-5 system based on parity, the system should reconstruct the block from the other blocks in the parity group.

Disk 0	Disk 1	Disk 2	Disk 3	Disk 4	
0	1	2	3	P0	
5	6	7	P1	4	
10	11	P2	8	9	
15	P3	12	13	14	
P4	16	17	18	19	

RAID-5 With Rotated Parity

Detecting Corruption: The Checksum

• How can a client say that a block has gone bad?

D Using **Checksum mechanisms**:

 This is simple the result of a function that takes a chunk of data as input and computes a function over said data, producing a small summary of the contents of the data.

Common Checksum Functions (Cont.)

- Different functions are used to compute checksums and vary in strength.
 - One simple checksum function that some use is based on **exclusive or(XOR)**.

_								
	66	be f6	3a 40	ecef 2c	al4 8a92	4cd ba	65e c4	3
get the following:	ary, we	in bir	v them	If we view	,			
	1101	1100	0100	1100	1110	0101	0110	0011
	0010	1001	1010	1000	0100	0001	1010	1011
	1010	0011	1100	0010	1111	1110	1100	1110
	0110	0110	0110	1111	1110	1011	0000	0100
llting checksum will be:	he resu	what	to see	It is easy				
	0011	0000	0100	1001	1011	0001	0000	0010
J								L

The result, in hex, is 0x201b9403.

- XOR is a reasonable checksum but has its limitations.
 - Two bits in the same position within each checksumed unit changed the checksum will not detect the corruption

- Addition Checksum
 - This approach has the advantage of being fast.
 - Compute 2's complement addition over each chunk of the data, ignoring overflow
 - Bad if data is shifted
- Fletcher Checksum
 - Compute two check bytes, s1 and s2.
 - Assuming a block D consists of bytes d1...dn; s1 is simply in turn is
 - s1 = (s1 + di) mod 255 (compute over all di);
 - s2 = (s2 + s1) mod 255 (again over all di);
- Cyclic redundancy check(CRC)
 - Treating D as if it is a large binary number and divide it by an agreed upon value k.
 - The remainder of this division is the value of the CRC
 - Easy to implement with binary modulo operations
- No perfect checksum [4KB --> 8bytes] (prob. **collisions** != 0)

D The disk layout without checksum:

D0 D1 D2 D3 D4 D5 D0	26
----------------------	----

• The disk layout **with checksum**:

• Store the checksums packed into 512-byte blocks.

CID01 CID11 CID32 CID32 CID31 CID32 CID31	D2	D3	D4
---	----	----	----

- When reading a block D, the client reads its checksum from disk
 Cs(D), stored checksum
- Computes the checksum over the retrieved block D, computed checksum Cc(D).
- **D** Compares the stored and computed checksums;
 - If they are equal (Cs(D) = Cc(D)), the data is in safe.
 - If they do not match (Cs(D) != Cc(D)), the data has changed since the time it was stored (since the stored checksum reflects the value of the data at that time).

- Modern disks have a couple of unusual failure-modes that require different solutions.
 - Misdirected write arises in disk and RAID controllers which the data to disk correctly, except in the *wrong* location (correct data in the wrong location)

 Lost Writes, occurs when the device informs the upper layer that a write has completed but in fact it never is persisted

- Solutions
 - 1. Write verify or read-after-write
 - 2. Adds checksums elsewhere. Zettabyte File System (ZFS) includes checksum for each file system inode and indirect block for every block included within a file
 - Every data block write lost will not match with the corresponding inode checksum
 - Still doesn't not prevent simultaneous lost writes in inode and data!

Scrubbing

- When do these checksums actually get checked?
 - Some amount when the files are accessed by the apps
 - Most data is rarely accessed, and thus remain unchecked.
- **D** To remedy this problem, many systems utilize **disk scrubbing**.
 - By **periodically reading** through every block of the system
 - Checking whether checksum are still valid
 - Reduce the chances that all copies of certain data become corrupted

- **•** Two distinct kinds of overheads : **space** and **time**
- **D** Space overheads
 - **Disk itself**: A typical ratio might be an 8byte checksum per 4KB data block, for a 0.19% on-disk space overhead.
 - Memory of the system: This overhead is short-lived and not much of a concern.
- **D** Time overheads
 - CPU must compute the checksum over each block
 - To reducing CPU overheads is to combine data copying and checksumming into one streamlined activity (like in networking)

This lecture slide set was initially developed for Operating System course in Computer Science Dept. at Hanyang University. This lecture slide set is for OSTEP book written by Remzi and Andrea at University of Wisconsin.
